

INMO (Indian National Mathematical Olympiad) - Solutions - 2024

1. In triangle ABC with  $CA = CB$ , point E lies on the circum circle of ABC such that  $\angle ECB = 90^\circ$ . The line through E parallel to CB intersects CA in F and AB in G. Prove that the centre of the circum circle of triangle EGB lies on the circum circle of triangle ECF.

**Solution:**

Let  $C_1$  be the circumcentre of  $\triangle ECF$ , then  $C_1E = C_1F = C_1C$ .

Let  $E'$  be the reflection of E w.r.t  $C_1$ .

We have  $AF = GF$

OC is angular bisector of  $\angle C$  (as  $\triangle ABC$  is isosceles)

$$\angle OCE = 90^\circ - \frac{\angle C}{2}$$

$$\angle OEC = 90^\circ - \frac{\angle C}{2}$$

$$\angle COE = \angle C$$

$$\angle CAE = \frac{\angle C}{2}$$

$$AF = FE, AF = GF \implies GF = FE$$

Now,  $GF = FE$ ,  $EC_1 = C_1E'$  &  $\angle GEE' = \angle C_1EE'$  is common

$$\triangle FEC_1 \cong \triangle GEE' \implies EE' = E'G$$

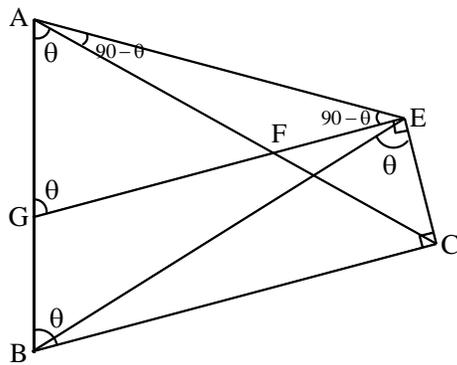

From the similarity, we have  $\angle EGE' = \angle BGE' = 90^\circ - \frac{\angle C}{2}$

$$\angle BE' = \angle GE' = \angle EE'$$

This means  $E'$  is the circumcentre of  $\triangle BGE$

But  $E'$  is also the reflection of E about  $C_1$ , and hence  $E'$  lies on the circumcircle of  $\triangle FEC$ .

**Alternative solution :**

**Given that**  $BC \perp EC$  and  $GE \parallel BC$

$$\angle BCE = \angle CEG = 90^\circ$$

$$CA = CB$$

$$\angle BAC = \angle CBA$$

But as  $ABCE$  is cyclic, we have

$$\angle BEC = \angle BAC \quad \& \quad \angle BAC + \angle BCE = 180^\circ$$

$$\angle BAC = 90^\circ = 180^\circ - \angle BCE$$

$$\angle BAC = 90^\circ$$

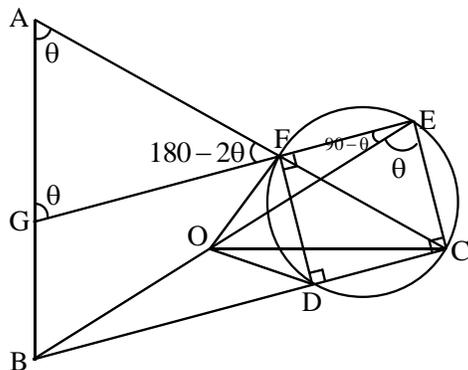

$$\angle FAE = 90^\circ$$

As  $GE \parallel BC$ ,  $\angle AGE = \angle ABC$

$$\angle AEG = 90^\circ$$

$$\angle AFE = 2 \times \angle AGE$$

But as  $\triangle AGE$  is right angled and  $F$  lies on hypotenuse, we have  $E$  is circumcentre of  $\triangle AGE$   $GF = FE$

Draw  $FD \perp GE$   $D$  lies on the circle

Let  $O =$  mid point of  $BE$

As  $\angle BCE = 90^\circ$ ,  $BE$  is diameter and  $O$  is centre of  $\triangle ABC$

$$\angle BOC = 2 \angle BAC = 2\theta$$

$$\angle COE = 180^\circ - 2\theta$$

$$\angle CFE = \angle AFG = 180^\circ - 2\theta$$

But  $\angle CFE = \angle COE = 180^\circ - 2\theta$

So,  $\square COFE$  is cyclic and  $\square DOEC$  is cyclic

$$\angle DOE = \angle DCE = 180^\circ - 2\theta$$

$$\angle DOE = 90^\circ$$

So  $FD$  is perpendicular bisector of  $GE$

And  $DO$  is perpendicular bisector of  $BE$

$D$  is circumcentre of  $\triangle BGE$  lies on circumcentre of  $\triangle CFE$

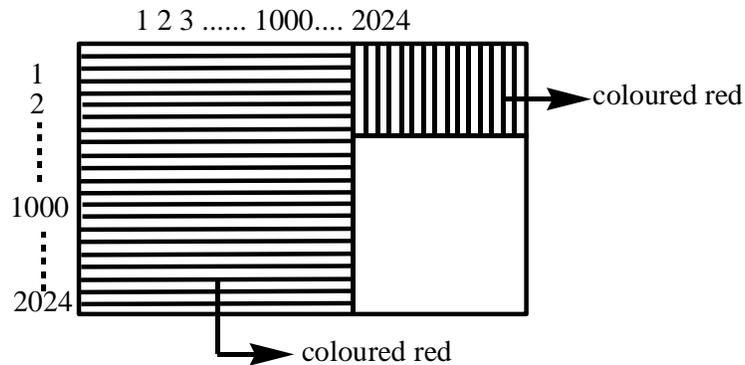

2. All the squares of a 2024 x 2024 board are coloured white. In one move Mohit can select one row or column whose every square is white, choose exactly 1000 squares in this row or column, and colour all of them red. Find the maximum number of squares that Mohit can colour red in a finite number of moves

**Solution:**

Mohit cannot select any row or column because it is clearly mentioned in the question that all the squares should be white. Without loss of generality assume Mohit first selected the rows. Then he should select 2024 rows. Now Mohit can select  $\leq 2024 - 1000 = 1024$  columns (Mohit can select 1024 columns if all rows are identically coloured)

$\therefore$  Mohit can choose a maximum of  $2024 + 1024 = 3048$  (including rows and columns)

Therefore Mohit selected  $3048 \times 100 = 3048000$  squares and coloured them. (Below is an example)

3. Let 'p' be an odd prime number and a, b, c be integers so that the integers

$$a^{2023} + b^{2023}, b^{2024} + c^{2024}, c^{2025} + a^{2025}$$

are all divisible by 'p'. Prove that 'p' divides each of a, b and c.

**Solution:**

Let  $p \times a$ , then  $p \times b$  and  $p \times c$  (trivial)

From question,

$$b^{2023} \equiv -a^{2023} \pmod{p} \rightarrow (1)$$

$$c^{2024} \equiv -b^{2024} \pmod{p} \rightarrow (2)$$

$$c^{2025} \equiv -a^{2025} \pmod{p} \rightarrow (3)$$

Multiply (1) by 'b' and substitute in (2)

$$c^{2024} \equiv a^{2023}b \pmod{p}$$

Multiply by 'c' and substitute in (3)

$$\boxed{a^2 \equiv -bc \pmod{p}}$$

From 1<sup>st</sup> equation,

$$a(a^2)^{1011} \equiv -b^{2023} \pmod{p}$$

$$ac^{1011} \equiv b^{1012} \pmod{p} \text{ [As } p \text{ won't divide } b]$$

$$a^2c^{1011} \equiv ab^{1012} \pmod{p}$$

$$c^{1012} \equiv -ab^{1011} \pmod{p}$$

$$c^{2024} \equiv a^2 b^{2022}$$

$$-a^{2025} \equiv a^2 b^{2022} c \quad [\text{Using 3}^{\text{rd}} \text{ equation}]$$

$$-a^{2023} \equiv b^{2022} c$$

$$b^{2023} \equiv b^{2023} c \quad [\text{Using 2}^{\text{nd}} \text{ equation}]$$

$$\boxed{b \equiv c \pmod{p}}$$

So, using 2<sup>nd</sup> equation,

$$c^{2024} \equiv -c^{2024} \pmod{p}$$

So,  $p/b$  and  $p/c \Rightarrow p/a$

Contradiction

So, 'p' has to divide each of a, b, c.

4. A finite set  $S$  of positive integers is called cardinal if  $S$  contains the integer  $|S|$ , where  $|S|$  denotes the number of distinct elements in  $S$ . Let  $f$  be a function from the set of positive integers to itself, such that for any cardinal set  $S$ , the set  $f(S)$  is also cardinal. Here  $f(S)$  denotes the set of all integers that can be expressed as  $f(a)$  for some  $a$  in  $S$ . Find all possible values of  $f(2024)$ .

Note: As an example,  $\{1, 3, 5\}$  is a cardinal set because it has exactly 3 distinct elements, and the set contains 3.

**Solution:** Considering the singleton cardinal set  $\{1\}$ . We see that  $f(1) = 1$ . The cardinal set  $\{1, 2\}$  gets mapped to  $\{1, f(2)\}$ , so  $f(2)$  must be 2 or 1.

**Case 1.** Suppose  $f(2) = 1$ . Now  $\{2, 2024\}$  is a cardinal set, and therefore so is  $\{1, f(2024)\}$ .

This means  $f(2024)$  is 1 or 2.

**Case 2.** Suppose  $f(2) = 2$ . The cardinal set  $f(\{1, 2, 3\}) = \{1, 2, f(3)\}$  shows that  $f(3) \in \{1, 2, 3\}$ , but the cardinal set  $f(\{2, 3\}) = \{2, f(3)\}$  proves  $f(3)$  cannot be 2. Thus there are two sub-cases.

**Subcase (i).**  $f(3) = 1$ . Then the set  $\{1, 3, 2024\}$  is cardinal, hence so is  $\{1, f(2024)\}$ , implying, as before,  $f(2024) \in \{1, 2\}$ .

**Subcase (ii).**  $f(3) = 3$ . In this case, we show via induction that  $f(n) = n$  for all  $n \in \mathbb{N}$ .

The base cases  $n = 1, 2, 3$  are already known. Now consider  $n \geq 4$ , and assume  $f(k) = k$  for all  $k < n$ . Consider the cardinal  $f(\{1, 2, \dots, n\}) = \{1, 2, \dots, n-1, f(n)\}$  which implies  $f(n) \in \{1, 2, \dots, n\}$ . However, consider the  $n-1$  element cardinal set  $\{1, 2, \dots, n\} \setminus \{n-2\}$ . For its image to be cardinal  $f(n)$  cannot equal any number in  $\{1, 2, \dots, n-1\} \setminus \{n-2\}$ ; else its cardinality would be  $n-2$ , which isn't in the set. So  $f(n) \in \{n-2, n\}$ .

Finally, consider the  $n-2$  element set  $\{1, 2, \dots, n\} \setminus \{n-1, n-3\}$ . If  $f(n) = n-2$ , its image would only have  $n-3$  and the induction is complete. In particular,  $f(2024) = 2024$ .

Thus the only possible values of  $f(2024)$  are 1, 2 and 2024.

5. Let points  $A_1, A_2,$  and  $A_3$  lie on the circle  $\Gamma$  in counter – clockwise order, and let P be a point in the same plane. For  $i \in \{1, 2, 3\}$ , let  $T_i$  denote the counter – clockwise rotation of the plane centred at  $A_i$ , where the angle of the rotation is equal to the angle at vertex  $A_i$  in  $\Delta A_1 A_2 A_3$ . Further, define  $P_i$  to be the point  $T_{i+2}(T_i(T_{i+1}(P)))$ , where indices are taken modulo 3 (i.e.,  $T_4 = T_1$  and  $T_5 = T_2$ ).

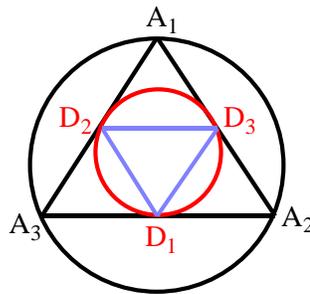

Prove that the radius of the circumcircle of  $\Delta P_1 P_2 P_3$  is at most the radius of  $\Gamma$ .

**Solution:** Fix an index  $i \in \{1, 2, 3\}$ . Let  $D_1, D_2, D_3$  be the points of tangency of the incircle of triangle  $\Delta A_1 A_2 A_3$  with its sides  $A_2 A_3, A_3 A_1, A_1 A_2$  respectively.

The key observation is that given a line  $\ell$  in the plane, the image of  $\ell$  under the mapping  $T_{i+2}(T_i(T_{i+1}(\ell)))$  is a line parallel to  $\ell$ . Indeed,  $\ell$  is rotated thrice by angles equal to the angles of  $\Delta A_1 A_2 A_3$ , and the composition of these rotations induces a half – turn and translation on  $\ell$  as the angles of  $\Delta A_1 A_2 A_3$  add to  $180^\circ$ . Since  $D_i$  is a fixed point of this transformation (by the chain of maps  $D_i \xrightarrow{T_{i+1}} D_{i+2} \xrightarrow{T_i} D_{i+1} \xrightarrow{T_{i+2}} D_i$ ), we conclude that the line  $\overline{PD_i}$  maps to the line  $\overline{P_i D_i}$ . But the two lines are parallel and both of them pass through  $D_i$  hence they must coincide, so  $D_i$  lies on  $\overline{PP_i}$ . Further, each rotation preserves distances, hence  $P_i$  is the reflection of P in  $D_i$ .

In other words, the triangle  $P_1 P_2 P_3$  is obtained by applying a homothety with ratio 2 and centre P to the triangle  $D_1 D_2 D_3$ . Thus, the radius of the circumcircle of  $\Delta P_1 P_2 P_3$  is twice the radius of the circumcircle of  $\Delta D_1 D_2 D_3$ . i.e., twice the radius of the incircle of  $\Delta A_1 A_2 A_3$ , which is known to be at most the radius of the circumcircle  $\Gamma$ .

**Remark.** The conclusion used the fact that in a triangle ABC with incentre I and in radius r, and circumcentre O and circumradius R, we have the inequality  $R \geq 2r$ . This is called Euler’s Inequality. The standard proof is that  $0 \leq OI^2 = R^2 - Pow(I, (O, R)) = R^2 - 2Rr$ . The last equality holds as  $Pow(I, (O, R)) = IA \cdot IM$  where M is the midpoint of minor arc  $\widehat{BC}$  in the circumcircle of ABC, and because  $IA = \frac{r}{\sin \frac{A}{2}}$  and  $IM = MB = \frac{a}{2 \cos \frac{A}{2}} = \frac{2R \sin A}{2 \cos \frac{A}{2}} = 2R \sin \frac{A}{2}$  by using “the trident lemma” and the double – angle sine formulas.

6. For each positive integer  $n \geq 3$ , define  $A_n$  and  $B_n$  as

$$A_n = \sqrt{n^2+1} + \sqrt{n^2+3} + \cdots + \sqrt{n^2+2n-1},$$

$$B_n = \sqrt{n^2+2} + \sqrt{n^2+4} + \cdots + \sqrt{n^2+2n}$$

Determine all positive integers  $n \geq 3$  for which  $[A_n] = [B_n]$ .

Note: For any real number  $x$ ,  $[x]$  denotes the largest integer  $N$  such that  $N \leq x$ .

**Solution:**

$$\text{Let } M = n^2 + \frac{1}{2}n$$

Case (i):

$$(B_n - A_n) = \sum_{k=1}^n (\sqrt{n^2+2k} - \sqrt{n^2+2k-1}) = \sum_{k=1}^n \frac{1}{\sqrt{n^2+2k} + \sqrt{n^2+2k-1}} < \sum_{k=1}^n \frac{1}{2n} = \frac{n}{2n} = \frac{1}{2}$$

Case (ii):

$$(A_n - n^2) = \sum_{k=1}^n (\sqrt{n^2+2k-1} - n) = \sum_{k=1}^n \frac{2k-1}{\sqrt{n^2+2k-1} + n} < \sum_{k=1}^n \frac{2k-1}{n+n} = \frac{n^2}{2n} = \frac{n}{2}$$

as  $\sum_{k=1}^n (2k-1) = n^2$ , proving  $A_n - n^2 < \frac{n}{2}$  or  $A_n < M$

Similarly,

$$(B_n - n^2) = \sum_{k=1}^n (\sqrt{n^2+2k} - n) = \sum_{k=1}^n \frac{2k}{\sqrt{n^2+2k} + n} > \sum_{k=1}^n \frac{2k}{(n+1)+n} = \frac{n(n+1)}{2n+1} > \frac{n}{2}$$

as  $\sum_{k=1}^n (2k) = n(n+1)$ , so  $B_n - n^2 > \frac{n}{2}$  hence  $B_n > M$

By Case (ii), we see that  $A_n$  and  $B_n$  are positive real numbers containing  $M$  between them. When 'n' is even,  $M$  is an integer. This implies  $[A_n] < M$ , but  $[B_n] \geq M$ , which means we cannot have  $[A_n] = [B_n]$ .

When 'n' is odd,  $M$  is a half-integer, and thus  $M - \frac{1}{2}$  and  $M + \frac{1}{2}$  are consecutive integers.

So the above two cases imply

$$M - \frac{1}{2} < B_n - (B_n - A_n) = A_n < B_n = A_n + (B_n - A_n) < M + \frac{1}{2}$$

This shows  $[A_n] = [B_n] = M - \frac{1}{2}$ .

Thus, the only integers  $n \geq 3$  that satisfy the conditions are the odd numbers and all of them work.
